

# **BFRMProject**

Jeffrey T. Chang, Joseph E. Lucas

3 January 2011

**Summary:** This calculates, on a new data set, the scores for the factors found by the BFRMFactor module. The BFRMFactor module will decompose a data set into a series of underlying factors. This module will calculate the scores of those factors in additional data sets, a procedure called projecting the factors.

**Parameter:** dataset

Factors will be projected onto this data set. This should be in PCL or GCT format. Some other data formats will also be accepted.

**Parameters:** bfrm\_model

This is the *bfrm\_model.zip* file that contains the factors to project. This file should have been generated by the BFRMFactor module.
